**Does urbanization filter vegetation through the soil? A spatially validated test with global soil maps in a West African floodplain city**

Ochoche Shaibu, Anatoly A. Kirichuk. *Environmental Earth Sciences*. Corresponding author: shaibuochoche2014@gmail.com

# Fig. S1

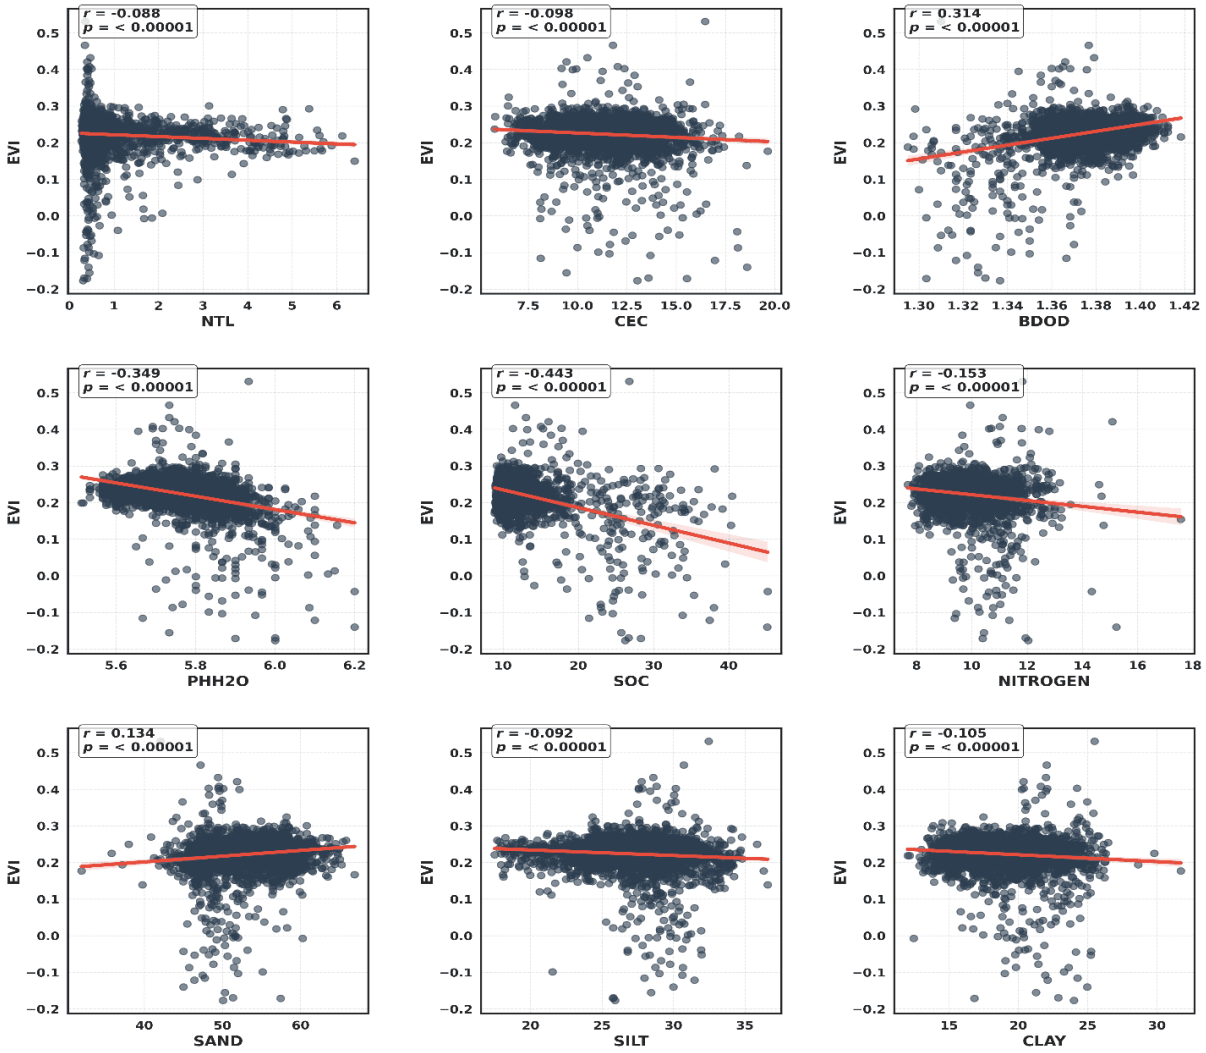

**Fig. S1** Bivariate response of EVI to urban intensity (NTL) and each SoilGrids property, with linear trends ($n = 3{,}507$ grid cells of 500 m). The $p$ values treat cells as independent and are therefore nominal (see main text, Sect. 3.8, for the effective sample size).

## S2. Scan-order structure of the archived grid table

The archived table stores cells in Google Earth Engine `coveringGrid` order. The autocorrelation of nighttime radiance between consecutive rows was 0.971 and peaked again at a lag of 70 rows (0.919), the mean length of one east–west scan line; the analogous values for EVI were 0.808 and 0.504. Cells with EVI $< 0.05$ (the Benue channel) all fell between rows 2,176 and 2,924 (about 11 scan lines). These properties justify the latitude-band validation and clustering used in the main text. The coordinate-based extension (`scripts/gee/makurdi_export_v2.js`) re-exports the same grid with centroid coordinates and verifies row-for-row identity with the archived table.
